Interpretation Request #17

Topic: pthread_attr_setschedparam **Relevant Clauses:** 13.5.1.2

These functions do not provide for an EPERM error condition. All other scheduling functions have an EPERM to signify that the user doesn't have permission to set these particular scheduling attributes. Similarly, pthread_create() also does not contain an EPERM. This behavior requires implementations to let anyone use the SCHED_FIFO/SCHED_RR policies and priorities, even though all other functions trying to use them may return EPERM. What is the correct behavior? Are there supposed to be EPERM error returns for these functions? Should there be an error of EPERM for pthread_create() instead? Should all three functions have an EPERM error return?

Interpretation Response

The standard is clear that setting the scheduling policy or priority values in the scheduling attribute object does not actually change the value for any threads. It is only when the attribute object is used in a pthread_create that the parameters are used and it is at that time that the parameters shall be consistent. The scheduling policy and priorities of an existing thread may be changed using the pthread_setschedparam function which requires both a policy and a priority. The standard is silent on what permissions, if any, an application must have to perform a pthread_create. Conforming implementations are free to not restrict access or to restrict access and return EPERM if detected. Conforming applications must handle this case.

Rationale for Interpretation

It is not possible to detect or report EPERM error conditions when modifying the scheduling parameter attributes. The intent was that attributes objects may be thought of as

user data structures, and the various set and get functions might be nothing more than macros that assign (or read) data to or from members of that structure.
